

PATENT APPLICATION

NAVY CASE NO. 95926

APPARATUS AND METHOD FOR PROVIDING TRUE GEODETIC COORDINATES**CROSS-REFERENCE TO RELATED APPLICATIONS**

5 This application claims priority under 35 U.S.C. §119(e) of U.S. provisional application having serial number 60/540,901 filed on January 28, 2004, which is hereby incorporated by reference. This application is co-pending and was concurrently filed with U.S. patent application having Navy Case No. 84647.

10 **STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH OR**
DEVELOPMENT

The invention described herein may be manufactured and used by or for the government of the United States of America for governmental purposes without the payment of any royalties thereon or therefor.

15

BACKGROUND OF THE INVENTION

For weapons systems to be effective, the location of a target must be known in a coordinate system, such as longitude, latitude and elevation. These coordinates must be extremely accurate in order to properly guide a weapon and to avoid collateral damage.

20 In the past attempts have been made to improve the determination of coordinates. Often this includes teams of observers equipped with various and cumbersome portable systems to either determine target position coordinates or to designate the target by laser illumination in the

case of laser homing systems. Despite these advances teams are still equipped with maps and are required to perform calculations in the field.

In addition, determining a true bearing to a target or a location is a concern due to the difference between magnetic readings of raw and true directions. The difference between true north and magnetic north at a location is called magnetic declination. Correction of magnetic declination is extremely important as the difference in degrees on a 0-360 degree scale between the bearing to the magnetic north pole and the bearing to the geographic north pole, or true North Pole in many areas of the earth may amount up to about 30 degrees and above. Due to declination, maps are printed marked with the local values of declination.

Known instruments for aiding in the use of maps, are very limited in their usefulness, particularly for military purposes. One such limitation is that they are applicable to a single scale map because each instrument is calibrated for use with one of several military scaled maps, as for example 1:25,000, 1:50,000 or 1:125,000. Another limitation of known instruments, particularly for military uses, is that the user has a need in the effective use of a map to make arithmetical computations and, therefore, military recruits must undergo extensive training in map reading. Some of the arithmetical computations involve converting magnetic azimuths to grid azimuths and conversion to back azimuths when it is desired to locate on the map an unknown point from two known points, which functions are referred to as "resection" and "intersection." Also, in determining the total distance along a sinuous path, e.g. a road or railroad track, the user must add the straight portions of the path between the curved portions. A further limitation of known map reading devices is that the artillery uses instruments in which angular directions are measured in mils rather than degrees for more accurate aiming of the weapons.

Thus, artillery personnel and those spotting for artillery units must have special map reading and plotting instruments. Obviously, where in the use of heretofore known map reading instruments computations are required, the need for paper and/or a writing implement poses a problem, particularly under actual field conditions where paper and a writing tool is not, always available to the map user. Also, map reading and plotting instruments of heretofore known types require the user to draw lines on a map and, in absence of available paper, the user may use the map for making computations. These writings on a map lead to short map life and leaves marks which, even if erased, are visible or can be made visible and may give aid to an enemy if the map is captured.

Determining target coordinates in the field is cumbersome and prone to error using the methods described. Accordingly, there is a need for rapidly calculated, accurate true coordinates, generated without maps and hand calculations, which may be used for various applications including but not limited to directing weapons to a target.

SUMMARY OF THE INVENTION

An embodiment of the invention includes an apparatus for providing true geodetic coordinates of a target position (TGT) using an image database including a portable personal computing device having means to accept input, and output data and commands and a processor configured to execute a process corresponding to the input, output data and commands. The process includes accepting input of true geodetic coordinates of an own position (OP), accepting input of raw coordinates of a reference point (RP), and accepting input of true coordinates of RP obtained from the image database. The process further includes computing exact local magnetic declination

variance between the raw coordinates of RP and the true geodetic coordinates of RP, accepting

input of raw coordinates, inclination and range of said target position (TGT), computing the true geodetic coordinates of TGT utilizing the exact local magnetic declination variance, and outputting the true geodetic coordinates, inclination and range of the TGT.

5 Another embodiment of the invention includes a method for providing true geodetic coordinates of a target position (TGT) using an image database including providing a portable personal computing device having means to accept input, and output data and commands, providing a processor configured to process the input and the commands. The process includes, accepting input of true geodetic coordinates of an own position (OP), accepting input of raw coordinates of a
10 reference point (RP), accepting true geodetic coordinates of the RP, the true coordinates of RP being obtained from the image database, and computing exact local magnetic declination variance between the raw coordinates of RP and the true geodetic coordinates of RP. The process further includes accepting input of raw coordinates, inclination and range of the target position (TGT), computing the true geodetic coordinates of TGT utilizing the exact local magnetic declination
15 variance, and outputting the true geodetic coordinates, inclination and range of TGT.

 Another embodiment of the invention includes a computer program product, embodied on a computer readable medium, for providing true geodetic coordinates of a target position (TGT) using an image database including a computer code embedded in a portable personal computer (PC) having a computer program code causing the PC to interface with a user and with
20 other electronic medium, computer code for accepting input and commands and for outputting data, computer code to execute a process corresponding to the input and commands. The process includes, accepting input of true geodetic coordinates of an own position (OP), accepting input of

raw coordinates of a reference point (RP), accepting true geodetic coordinates of the RP, the true coordinates of RP being obtained from the image database, and computing exact local magnetic declination variance between the raw coordinates of RP and the true geodetic coordinates of RP.

The process further includes accepting input of raw coordinates, inclination and range of the target position (TGT), computing the true geodetic coordinates of TGT utilizing the exact local magnetic declination variance, and outputting the true geodetic coordinates, inclination and range of TGT.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a functional flowchart of the basic functions of the Precision Strike Suite (PSS) according to an embodiment of the invention.

FIGs. 2A-2D are screen captures of displays generated by embodiments of PSS.

FIG. 3 is a functional flowchart of the basic functions of the Reference Point Method (RPM) according to an embodiment of the invention

FIG. 4 is a screen capture of a display generated by an embodiment of RPM on a personal computing device.

DESCRIPTION OF EMBODIMENTS OF THE INVENTION

Embodiments of the present invention include an apparatus and method for providing true geodetic coordinates for locations, which may be used in targeting of weapons. It should be understood that the examples and embodiments described herein are for illustrative purposes only and that various modifications or changes in light thereof will be suggested to persons skilled in the art and are to be included within the spirit and purview of this application and the scope of the appended claims.

An embodiment of the invention includes a rugged handheld personal computer (PC)

such as, for example Panasonic Toughbooks TM CF-18, CF-27, CF-34, CF-50, CF-72; IBM A-

21P, A-31P, and Dell Inspiron TM laptops, housed in portable, tough, resilient cases. The PC

runs the Precision Strike Suite (PSS) and the Reference Point Method (RPM) programs that may

5 be windows based input and display programs that provide a user friendly interface to receive

input and display results. The PC may receive and input information via other means such as, for

example, USB/serial ports, or a touch screen. Those of ordinary skill in the art will readily

acknowledge that changes and codification may be made to the touch screen, keyboard or other

input/output options without departing or diverting from the scope of embodiments of the present

10 invention.

Generally, a portable personal computer (PC) system includes a bus and/or other

communication mechanisms for communicating information, and a processor coupled with the

bus for processing information. The PC also includes a main memory means such as, for

example, random access memory (RAM) or other dynamic storage device, coupled to the bus for

15 storing information and instructions to be executed by the processor. Main memory also may be

used for storing temporary variable or other intermediate information during execution of

instructions to be executed by the processor.

The PC further includes a read only memory (ROM) and/or other static storage device

coupled to the bus for storing static information and instructions for processor. A storage device

20 such as, for example, a magnetic disk or optical disk, is provided and coupled to the bus for

storing information and instructions. The PC may be coupled via the bus to a display means,

such as, for example, a cathode ray tube (CRT), for displaying information to a computer user.

An input device, including alphanumeric and other keys, is coupled to the bus for

communicating information and command selections to the processor. Another type of input

user device is cursor control, such as, for example, a mouse, an optical mouse, a trackball, touch screen, touch pad, or cursor direction keys for communicating direction information and

5 command selections to the processor and for controlling cursor movement on the display.

Precision Strike Suite (PSS)

An embodiment of the present invention utilizes the Precision Strike Suite (PSS). PSS

performs tasks including but not limited to the generation of true geodetic coordinates and

elevation of an item or a location, utilizing a stereo image database. PSS is loaded onto a PC

10 along with a stereo image database, such as, for example, the Digital Point Positioning Database

(DPPDB). DPPDB is a stereo image based product having parametric support data, compressed

reference graphics and high resolution optical imagery stereo pair sets each covering a 60 x 60

nautical mile area. PSS generates the precise true geodetic coordinates and elevation of any

identifiable point or target contained within the area provided by the image database. In an

15 embodiment of the invention PSS is written in Borland language and operates as a windows

based application. But those skilled in the art would recognize that PSS may be written in other

computer languages without departing from the embodiments of the invention.

Referring to the drawings, wherein elements are identified by numbers and like elements are identified by like numbers throughout the figures, **Fig. 1** shows a functional flowchart of the

20 basic functions of the PSS program. In an embodiment of the present invention, an initial

coordinate for the area of interest is inputted **110**. This may be the user's "own position" (OP) or

any other location. According to an embodiment of the present invention, this initial coordinate

may be in the form of the World Geodetic Survey 1984 (WGS-84) or a Military Grid reference

System (MGRS). This initial coordinate may be obtained from one of numerous sources known in the art, for example maps, charts, or Global Positioning System (GPS) receivers such as, for example, Precise Lightweight GPS Receiver (PLGR) or eTrex ®. In other embodiments of the

5 invention sources of the initial coordinates include but are not limited to a tactical image from sensors (such as, for example, Advanced Targeting Forward Looking Radar (ATFLIR)), from targeting pods (such as, for example, Low Altitude Navigation and Targeting Infrared for Night (LANTIRN)), or mapping systems (such as, for example, FalconView). The initial coordinate is entered as a geodetic location key within the PSS GUI extract dialog box. See **Fig. 2A**. This

10 initial coordinate may be entered in a variety of ways including, but not limited to, manually, via keyboard, transferred electronically (such as, for example, from a handheld GPS system), or internally between applications such as, for example, from an XML application.

PSS searches through the stereo image database installed on the PC for an image that encompasses the initial coordinate. PSS extracts the set of digital stereo images **120** from the
15 database. PSS places the digital stereo imagery and the specific support data for the imagery in an accessible form in the PC system memory **130** and displays them **140** as first and second side by side images in parallel windows on the PC screen and centered on the initial coordinate. The PSS displays how close the imagery center is to the initial coordinate. (The coordinates may differ due to rounding errors or differences in resolution size, etc.) The stereo images may be
20 centered or scrolled around using buttons on the windows interface, “grabby hand”, or by other display control means known in the art.

Subsequently, in an embodiment of the present invention, locations may be on the stereo

images by using a movable screen cursor available in each image and clicking on it. This is

known in the art as creating a “marker” **150**. When a marker is created on the first of the set of images, PSS may be requested to autocorrelate the cursor location and designate the exact same cursor location in the second of the set of images and match the first marker. The autocorrelation

5 uses a complex edge-gradient frequency domain correlation at full resolution of the left and right stereo pair. The last marker modified is the “active” marker. This active marker may be a “target position” (TGT), a “reference position” (RP), or the “own position” (OP). See **Fig. 2B**. This

location is accepted or adjusted as necessary **160**. It is noteworthy that the PSS will display a message if the coordinates sought are OP in case there is an error for safety reasons. The

10 markers are shown on the display of the stereo imagery set. They may be designated with different colors or shapes or made invisible on the screen via drop down menus as is well known in the art.

After markers have been set the “Get Coordinate” button on PSS **170** is selected to generate a geodetic coordinate for the active marker. PSS produces the exact geodetic

15 coordinates and elevation in a chosen reference system (such as, for example, World Geodetic System 1984 (WGS-84) or Military Grid Reference System (MGRS)). See **Fig. 2C**. The format

of the coordinates may be changed via selections on drop down menus. This output may be displayed or electronically transmitted to other equipment or to other remotely located personnel

or command center **180**. This transmission or output may be effected by many output means

20 including, but not limited, to via USB/serial connections, via a storage medium, via PCMCIA modem card and radio, and high speed data links.

Once the PSS has markers selected there are many options available. Some embodiments

include, but are not limited to: estimating a coordinate of a point based on the coordinates of two known reference points; calculating range, level range, bearing, inclination, or delta elevation between any two markers in various units such as for example, feet, meters, or degrees; or calculating coordinates of a new target position by entering the range and bearing to TGT measured from OP. See **Fig. 2D**. In an embodiment the TGT coordinates may be corrected for magnetic variance using the exact local magnetic declination variance values stored in tables on the PC or generated by the Reference Point Method (RPM) **190** (described below).

In addition many user preferences may be set under a drop down tools menu including but not limited to, startup coordinates and/or, input/output options. The display may be optimized via a graphics menu to add features including but not limited to displaying a compass, displaying coordinates on the stereo images, rotating imagery to show North up, and/or displaying radius rings around TGT. As previously noted, PSS may interact with other programs using the "Open XML file" command from the File drop down menu (XML stands for eXtensible Markup Language). Information such actual coordinate, coordinate type (friend or target), and coordinate accuracy (pedigree of how coordinate was derived) may be transferred between PSS and other programs via this option.

Another embodiment of the invention includes a method for providing true geodetic coordinates of a target position using an optical stereo image database including providing a portable personal computing device (PC) having means to accept input and commands, means to output, a memory means, and means to display a set of optical stereo images, side by side, from an optical stereo image database, including a first image and a second image, and providing a processor configured to maintain a stereo image database including optical stereo imagery with corresponding

geodetic data, and to execute a process corresponding to input and commands. The process

includes accepting input of geodetic coordinates of an own position (OP), extracting the set of stereo images centered around the OP from the stereo image database and storing the images in the

memory means. The process further includes displaying the stereo images on the display means and

5 displaying a first marker corresponding to the OP on each of the first and second images, accepting

input of target position (TGT) on the first stereo image and displaying a second marker

corresponding to the TGT on the first image, autocorrelating and displaying the second marker

corresponding to the TGT on the second stereo image. The process further includes receiving

approval of the selection of TGT, computing the true geodetic coordinates and elevation for the

10 TGT including correcting the geodetic data from the optical stereo image database for local

magnetic declination variance, and outputting the true geodetic coordinates, inclination and range of

TGT.

Another embodiment of the invention includes a computer program product, embodied on a computer readable medium, for providing true geodetic coordinates of a target position using

15 an optical stereo image database including a computer code embedded in a portable personal

computer (PC) having a computer program code causing the PC to interface with a user and with

other electronic medium, a computer code for receiving input and commands and for outputting

data, a computer code for displaying a set stereo images side by side, from the optical stereo

image database, having a first image and a second image, a computer code for configuring a

20 processor to maintain the optical stereo image database including at least one set of the stereo

images with corresponding geodetic data, and a computer code to execute a process

corresponding to the input and commands. The process includes accepting input of geodetic

coordinates of an own position (OP), extracting the set of stereo images centered around the OP

from the stereo image database and storing the images in the memory means. The process further

includes displaying the stereo images on the display means and displaying a first marker

corresponding to the OP on each of the first and second images, accepting input of target position

5 (TGT) on the first stereo image and displaying a second marker corresponding to the TGT on the

first image, autocorrelating and displaying the second marker corresponding to the TGT on the

second stereo image. The process further includes receiving approval of the selection of TGT,

computing the true geodetic coordinates and elevation for the TGT including correcting the geodetic

data from the optical stereo image database for local magnetic declination variance, and outputting

10 the true geodetic coordinates, inclination and range of TGT.

Reference Point Method

Fig. 3 shows a functional flowchart of the basic functions of the RPM program.

Reference Point Method (RPM) is written in C++ Borland Builder 6 for laptops and Microsoft

Visual Studio.Net for Windows CE devices such as, for example Compaq (HP) IPAQ™ model

15 3650 handheld PCs. RPM is installed on a separate handheld PC or operates alternatively in the

PSS program (described above). RPM functions to determine true geodetic coordinates of a

TGT not available to be displayed in an image database, such as, for example, movable

equipment. RPM generates a local magnetic declination variance that is exact for the location of

the OP, utilizing an optical stereo imagery database.

20 In an embodiment of the invention the “own position” (OP) is obtained via various means

such as, for example, a hand held GPS, map, or by the PSS. The OP coordinates are inputted

310 into a portable PC in the RPM software or marked as part of the operation of the PSS

Using various means described above, the true coordinates of a “reference point” (RP) are determined. The RP selected shall be a landmark that can be seen in the stereo imagery database and that can be seen through a laser range finder (LRF) from the OP. These coordinates
5 are entered **320** in the RPM dialog box (or are marked as RP in the PSS).

A LRF is fired from OP to RP. The LRF provides the range, bearing and inclination angle from OP to RP in raw coordinates. The raw coordinates of RP are inputted **330** in the RPM dialog box (or entered as magnetic coordinates in PSS). RPM compares the true coordinates of RP and the raw coordinates of RP and computes the exact local magnetic declination variance
10 for the OP **340**.

A LRF is fired from OP to “target position” (TGT). The LRF provides the range, bearing and inclination angle from OP to TGT in raw coordinates. The raw coordinates of TGT are entered in the RPM dialog box (or entered as magnetic coordinates in PSS) **350**. RPM generates the true geodetic coordinates of TGT using the local magnetic declination computed previously
15 and the inclination and range data from the LRF **360**. See Fig. 4. The true coordinates of TGT may be outputted, displayed or electronically transmitted to other equipment or to other remotely located personnel or command center **370**. This transmission or output may be effected by many output means including, but not limited to, via USB/serial connections, via a storage medium, via PCMCIA modem card and radio, and high speed data links.

20 In embodiments of the present invention the PSS and RPM programs are embodied on computer readable medium. A computed-readable medium is any article of manufacture that contains data that can be read by a computer. Common forms of computer-readable media

include, for example, floppy disk, a flexible disk, hard disk, magnetic tape, any other magnetic medium, a CD-ROM, DVD, any other optical medium, punch cards, paper tape, any other physical medium with patterns of holes, a RAM, a PROM, an EPROM, a FLASH-EPROM, any other memory chip or cartridge, or any other medium from which a computer can read. In addition, those skilled in the art would recognize that input and output in embodiments of the invention may occur via direct electronic means (such as, for example, by cable or by radio signal) rather than by direct user actions (such as, for example, keypad or touchpad entries).

Another embodiment of the invention includes a method for providing true geodetic coordinates of a target position (TGT) using an image database including providing a portable personal computing device having means to accept input, and output data and commands, providing a processor configured to process the input and the commands. The process includes, accepting input of true geodetic coordinates of an own position (OP), accepting input of raw coordinates of a reference point (RP), accepting true geodetic coordinates of the RP, the true coordinates of RP being obtained from the image database, and computing exact local magnetic declination variance between the raw coordinates of RP and the true geodetic coordinates of RP. The process further includes accepting input of raw coordinates, inclination and range of the target position (TGT), computing the true geodetic coordinates of TGT utilizing the exact local magnetic declination variance, and outputting the true geodetic coordinates, inclination and range of TGT.

Another embodiment of the invention includes a computer program product, embodied on a computer readable medium, for providing true geodetic coordinates of a target position (TGT) using an image database including a computer code embedded in a portable personal computer (PC) having a computer program code causing the PC to interface with a user and with

other electronic medium, computer code for accepting input and commands and for outputting

data, computer code to execute a process corresponding to the input and commands. The process

includes, accepting input of true geodetic coordinates of an own position (OP), accepting input of

raw coordinates of a reference point (RP), accepting true geodetic coordinates of the RP, the true

5 coordinates of RP being obtained from the image database, and computing exact local magnetic

declination variance between the raw coordinates of RP and the true geodetic coordinates of RP.

The process further includes accepting input of raw coordinates, inclination and range of the target

position (TGT), computing the true geodetic coordinates of TGT utilizing the exact local magnetic

declination variance, and outputting the true geodetic coordinates, inclination and range of TGT.

10 Although the description above contains much specificity, this should not be construed as
limiting the scope of the invention but as merely providing an illustration of embodiments of the
present invention. Thus the scope of this invention should be determined by the appended claims
and their legal equivalents.
